

AMENDMENTS TO THE CLAIMS

This listing of claims will replace all prior versions, and listings, of claims in the application:

Listing of Claims

1. (original) A reactive magnetron sputter deposition apparatus for coating a substrate comprising:
 - a vacuum chamber evacuated to a low pressure;
 - at least one pulsed DC magnetron positioned within said vacuum chamber and having a target source for sputtered particles;
 - means for positioning a substrate within said vacuum chamber a long throw distance away from and facing said at least one pulsed DC magnetron; and
 - means for providing a reactant gas at said target source to form said sputtered particles, wherein operation of the pulsed DC magnetron prevents target poisoning by the reactant gas at said target source.
2. (original) The apparatus of claim 1,
 - wherein said means for providing a reactant gas additionally provides an inert gas at said target source to form said sputtered particles.

3. (original) The apparatus of claim 1,
wherein said low pressure is below about 1 mTorr.
4. (original) The apparatus of claim 1,
wherein said long throw distance is greater than about 15 inches.
5. (original) The apparatus of claim 1,
wherein said target source is smaller than the width/area of the
substrate to be coated.
6. (original) The apparatus of claim 5,
wherein said target source is smaller than the width/area of the
substrate to be coated by at least a factor of three.
7. (original) The apparatus of claim 1,
wherein said long throw distance is a function of the width/area of the
substrate to be coated.
8. (original) The apparatus of claim 7,
wherein said long throw distance is additionally a function of the
number of said pulsed DC magnetrons/target sources utilized.

9. (previously presented) The apparatus of claim 1,
further comprising a plurality of pulsed DC magnetrons having a
corresponding plurality of target sources, wherein each additional target
source reduces the partial pressure of the reactant gas of every target source
without a corresponding reduction in the impingement ratio due to the
increase in total ionization provided thereby.

10. (canceled)

11. (previously presented) The apparatus of claim 9,
wherein said means for providing a reactant gas additionally provides
an inert gas at each target source to form said sputtered particles, and each
additional target source reduces the partial pressure of at least the reactant gas
for every target source without a corresponding reduction in the impingement
ratio due to the increase in total ionization provided thereby, wherein each
additional target source additionally reduces the partial pressure of the inert
gas for every target source to maintain said low pressure within said vacuum
chamber.

12. (canceled)

13. (original) A reactive magnetron sputter deposition process for coating large scale optics comprising:

providing a vacuum chamber evacuated to a low pressure;

providing at least one pulsed DC magnetron positioned within said vacuum chamber and having a target source for sputtered particles;

providing means for positioning a substrate within said vacuum chamber a long throw distance away from and facing said at least one pulsed DC magnetron; and

impinging said target source with a reactant gas to sputter said particles onto the substrate, wherein operation of the pulsed DC magnetron prevents target poisoning by the reactant gas at said target source.

14. (original) The process of claim 13,

further comprising impinging said target source with an inert gas at said target source to sputter said particles onto the substrate.

15. (original) The process of claim 13,

wherein said low pressure is below about 1 mTorr.

16. (original) The process of claim 13,

wherein said long throw distance is greater than about 15 inches.

17. (original) The process of claim 13,
wherein said target source is smaller than the width/area of the
substrate to be coated.
18. (original) The process of claim 17,
wherein said target source is smaller than the width/area of the
substrate to be coated by at least a factor of three.
19. (original) The process of claim 13,
wherein said long throw distance is a function of the width/area of the
substrate to be coated.
20. (original) The process of claim 19,
wherein said long throw distance is additionally a function of the
number of said pulsed DC magnetrons/target sources utilized.
21. (previously presented) The process of claim 13,
further comprising providing a plurality of pulsed DC magnetrons
having a corresponding plurality of target sources, wherein each additional
target source reduces the partial pressure of the reactant gas of every target
source without a corresponding reduction in the impingement ratio due to the
increase in total ionization provided thereby.

22. (canceled)

23. (previously presented) The process of claim 21,
further comprising impinging each target source with an inert gas to
form said sputtered particles, and wherein each additional target source
reduces the partial pressure of at least the reactant gas for every target source
without a corresponding reduction in the impingement ratio due to the
increase in total ionization provided thereby, wherein each additional target
source additionally reduces the partial pressure of the inert gas for every
target source to maintain said low pressure within said vacuum chamber.

24. (canceled)
